01 / FAMILY

Our transformer models

Three dense generations, one expert branch. All dense generations began with random weights.

Solid arrow: inherited weights
The MoE branch copies our trained Seed I feed-forward layers into expert banks and continues training.

Dashed arrows: design evolution
Seed II and Seed III use new random initialization. They do not inherit the preceding generation's weights.

Snapshot status
Seed I, its MoE branch and Seed II completed training. A host crash interrupted Seed III at update 5,590 of 6,000; its signed checkpoint at 5,500 survived.

The shared design

Each model is a causal, decoder-only transformer: it predicts the next token from preceding tokens. Input embeddings and the output projection share one learned matrix. All generations use rotary positional encoding (RoPE) and residual connections.

The learned token embeddings are separate from the fixed **Source Code Matrix** used in earlier vector reconstruction experiments. Transformer blocks and experts are modules inside the model, not network nodes.

02 / SPECIFICATIONS

What changed between generations

Values come from the saved run configurations and model implementations.

Configuration	Seed I	Seed I MoE	Seed II	Seed III
Parameters	5,773,824	10,495,488	40,645,120	125,857,536
Active / token	All	~7,349,760	All	All
Decoder blocks	6	6	12	18
Residual width	256	256	512	768
Query / KV heads	4 / 4	4 / 4	8 / 8	12 / 4
Head dimension	64	64	64	64
FFN width	1,024	1,024 / expert	1,408	2,048
FFN activation	GELU	GELU	SwiGLU	SwiGLU
Normalization	LayerNorm	LayerNorm	RMSNorm	RMSNorm
Context tokens	512	512	512	1,024
BPE vocabulary	4,096	4,096	4,096	16,384
Position encoding	RoPE	RoPE	RoPE	RoPE
Embedding / head	Tied	Tied	Tied	Tied

Capacity, context and computation

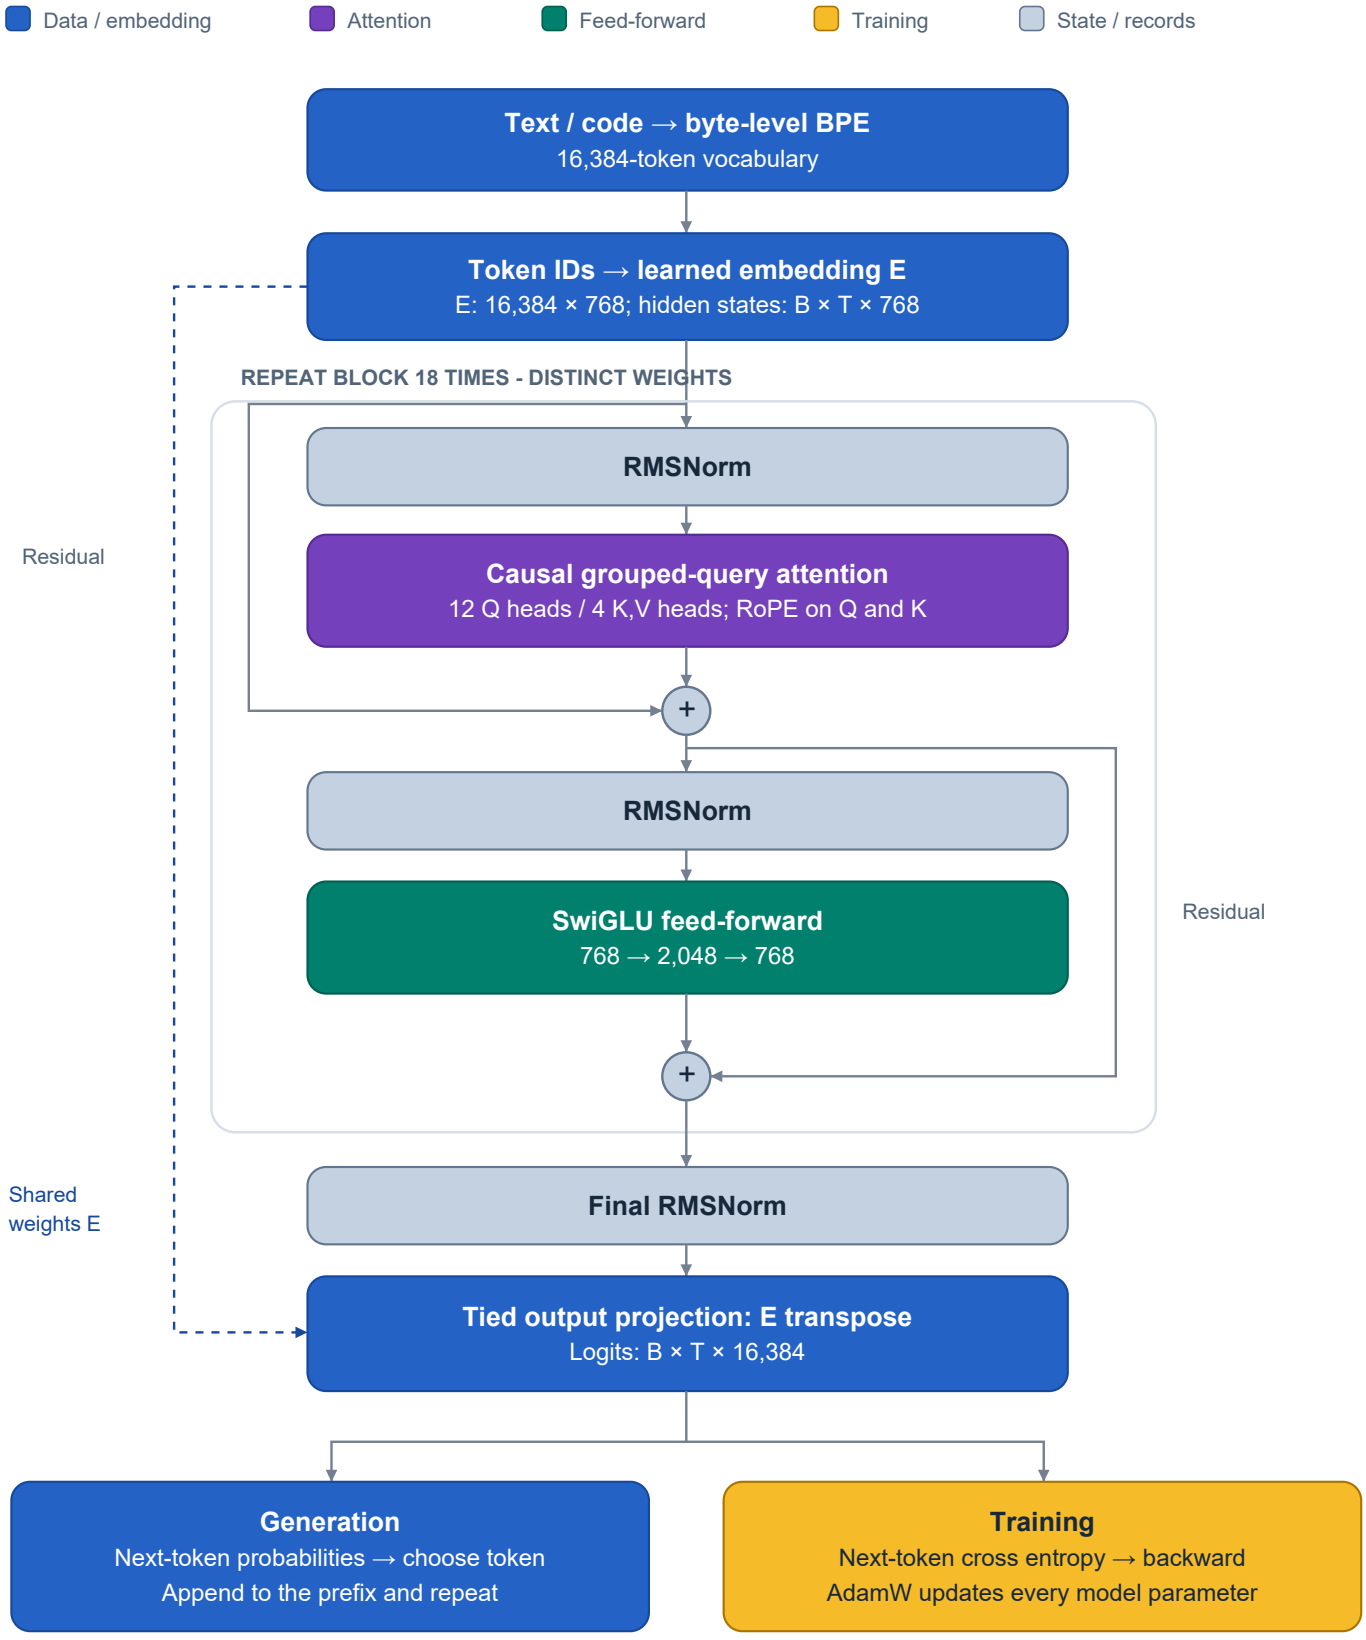

Depth is the number of successive transformer blocks. **Width** is the size of each token's evolving representation. **Context** limits how many tokens one forward pass can attend to. **Vocabulary** sets the number of possible next-token outputs.

The MoE parameter count includes every expert, while a token activates two experts in each expert layer. Seed III is dense: its SwiGLU gate acts on features and does not select experts. Every generation uses generative next-token pretraining.

03 / SEED III

From tokens to a continuation

B = batch size; T = sequence length, up to 1,024. The residual stream has width 768.

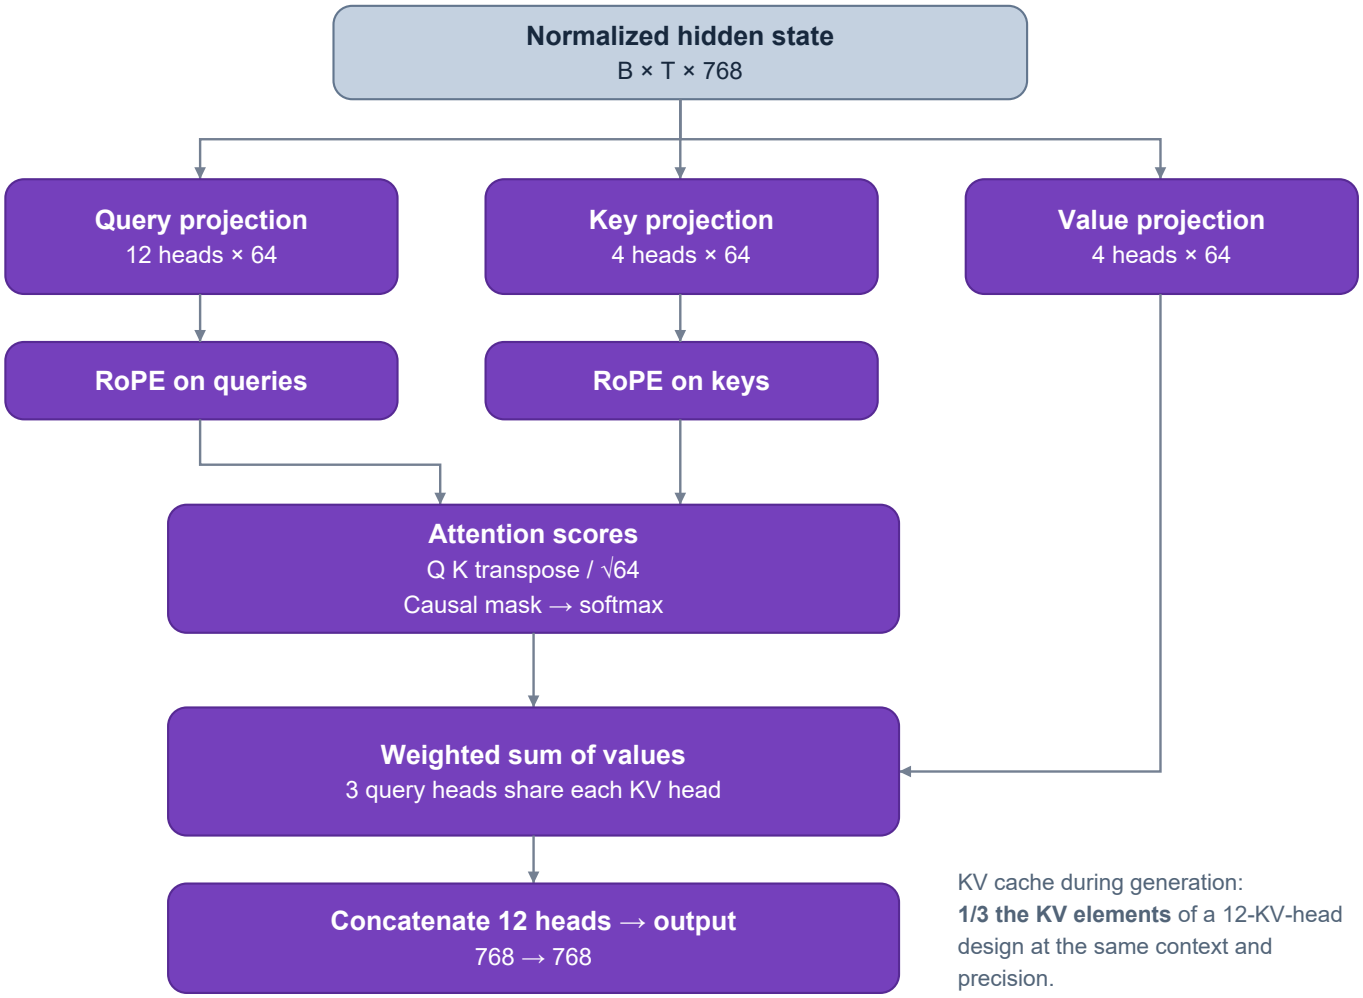

Padding targets are excluded from the loss. Generation uses the final position; training predicts at every valid position.

04 / INSIDE THE BLOCK

Attention and feature transformation

Attention mixes information between tokens; SwiGLU transforms each token's features.

KV cache during generation: **1/3 the KV elements** of a 12-KV-head design at the same context and precision.

RoPE rotates pairs of query/key coordinates by token position; it does not add learned position embeddings. The causal mask blocks future tokens. Keys and values are cached during generation.

SwiGLU: a dense feature gate

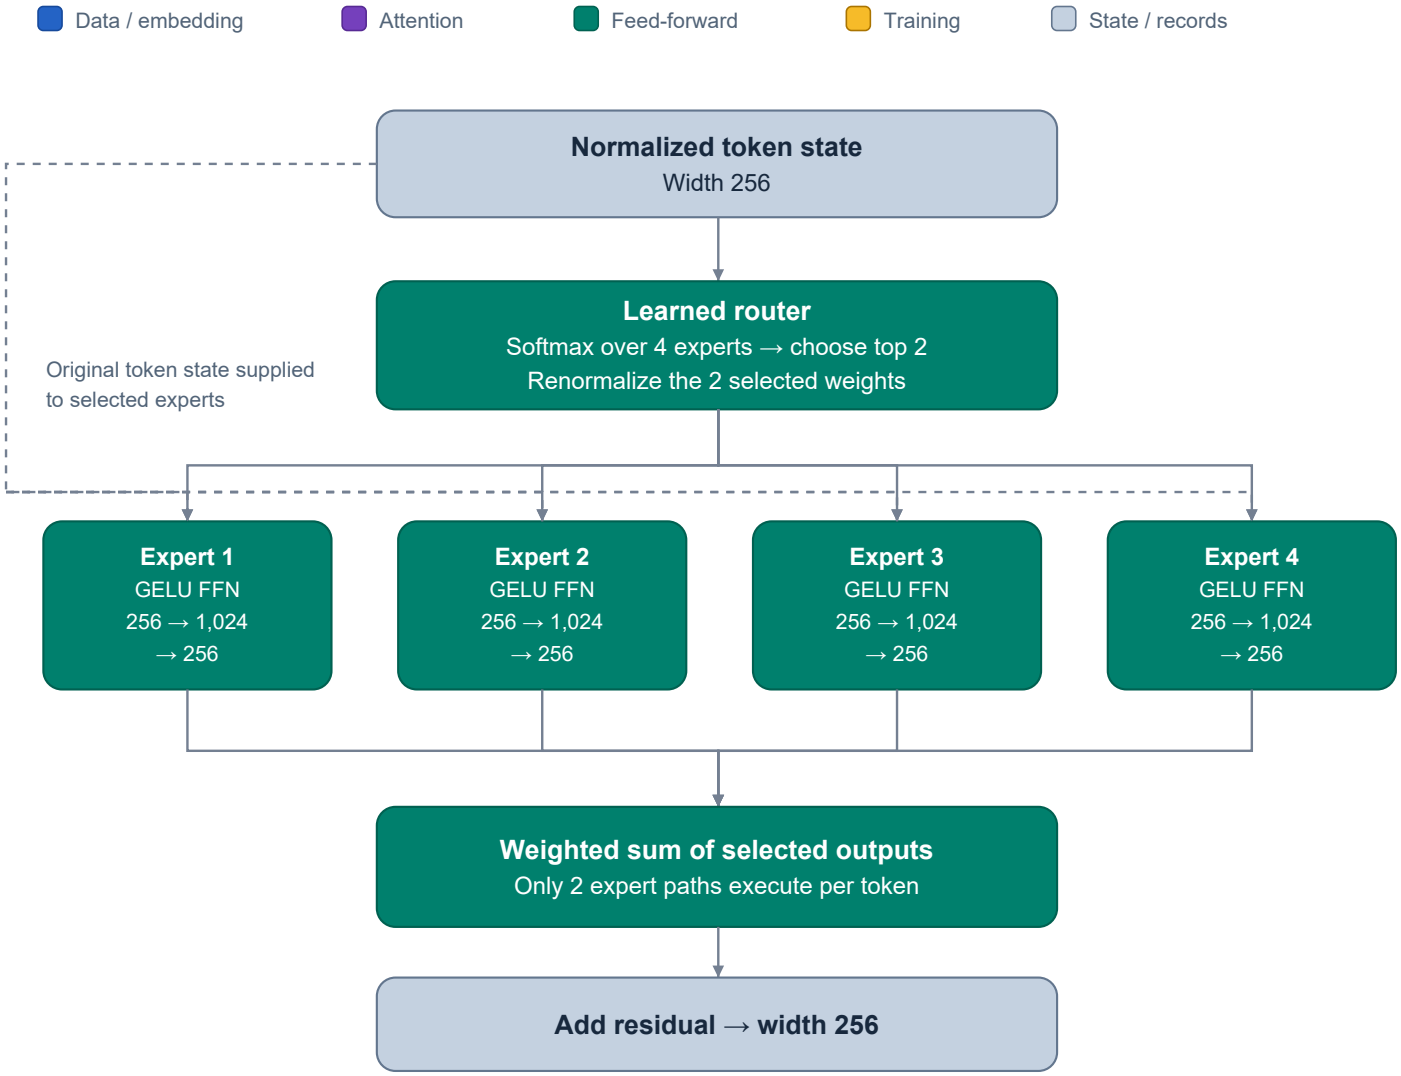

FFN(x) = down[SiLU(gate(x)) × up(x)] (elementwise product)
Both gate and up map 768 to 2,048 dimensions. All linear projections are bias-free; the model uses no dropout. RMSNorm epsilon is 1e-6.

05 / EXPERT BRANCH

How Seed I uses a mixture of experts

Expert banks replace the feed-forward transform in blocks 2, 4 and 6. Other blocks stay dense.

At conversion, every expert copies the corresponding trained dense feed-forward weights. The router is newly initialized, and AdamW state is reset. Continued training can differentiate experts. A stable expert-ID tie-break resolves equal router scores.

Optimization objective

$$L_{\text{next-token}} = -(1/N) \sum_{i \text{ in nonpadding targets}} \log p_\theta(x_i \mid x_{<i})$$

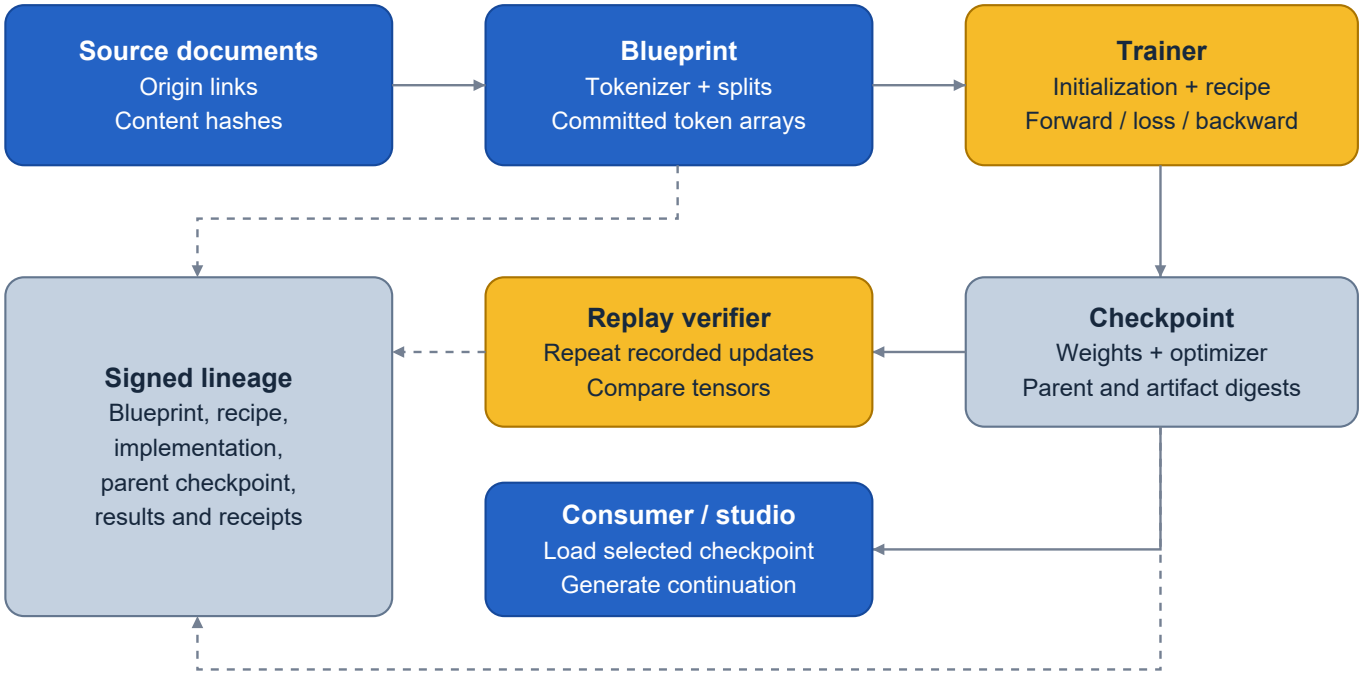

For the MoE branch: $L = L_{\text{next-token}}$ **+ 0.01 × mean router balancing loss**. The auxiliary term discourages unused experts. Validation loss selects the checkpoint.

These experts execute within one model process. Expert routing does not distribute them across network machines in this experiment.

06 / EXECUTION AND EVIDENCE

The model inside the network

Data lineage, model training, replay verification and inference are separate operations.

What the architecture diagram represents

The current main run uses one GPU for full-model backpropagation. Distributed DDP and Oracle adapter coordination have separate test records. Transformer depth does not imply deployment across that many nodes. Investigator source assessment runs after generation, outside the transformer.

Seed III uses AdamW, BF16 execution with FP32 master weights and optimizer state, and tied input/output weights. Residual output projections start at standard deviation 0.02 / $\sqrt{(2 \times 18)}$. Separate-process replay checks the recorded update interval against its checkpoint and optimizer state.

Implementation and run records

Seed I and MoE - src/dawl_scratch/model.py; docs/results/scratch-001/*-config.json

Seed II - src/dawl_seed/model.py; docs/results/scratch-003/dense/config.json

Seed III - src/dawl_lab/model.py; docs/results/seed-lab-001/run/recipe.json

The observed result

All 19 spans received insufficient evidence. The Investigator evaluated 54 retrieved passage pairs; one span had no candidate. The continuations and the 0.90 score / 0.20 margin thresholds were not changed to obtain other labels. No artificial outputs were added.

These are fictional continuations, sometimes incomplete or incoherent, rather than a factual question-answer benchmark. An invented scene may have no supporting passage even when well written. Retrieval coverage and the NLI evaluator also limit the result; this is not a measure of model accuracy.

Evidence that can be checked

All source hashes, exact excerpts, Blueprint membership, answer bindings and signed receipts passed verification. A fresh CPU process with no network or signing keys reproduced all 54 NLI outputs and verdicts exactly. This is replay within the same hardware/runtime cohort.

The bundle preserves the prompt, sampler, checkpoint identity, unchanged output, selected spans, origin links, complete passages and semantic scores. Checkpoint identity in the collection is a consumer assertion; this NLI replay does not re-run model generation or training.

Recorded inputs and replay: docs/results/seed-architecture-samples-002/. The earlier 32-token experiment remains intact in seed-architecture-samples-001/.
